The Geometry of Linear Equations
(MIT Gilbert Strang)

n linear equations, n unknowns

$$2x - y = 0$$
$$-x + 2y = 3$$

$$\begin{bmatrix} 2 & -1 \\ -1 & 2 \end{bmatrix}\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 0 \\ 3 \end{bmatrix}$$

$$A \qquad X = b$$

Goal: Describe
- > row picture
- *> column picture
- > Matrix form – algebra form

linear equation $\Rightarrow Ax = b$

Row Picture

$2x - y = 0 \; r_1$
$-x + 2y = 3 \; r_2$

$(1,2)$ solution

$(0,0)$

What would be all the linear combinations
of $x\begin{bmatrix} 2 \\ -1 \end{bmatrix} + y\begin{bmatrix} -1 \\ 2 \end{bmatrix} = \begin{bmatrix} 0 \\ 3 \end{bmatrix}$ be?
There are infinite solutions to this system

$$2x - y = 0$$
$$-x + 2y - 2 = -1$$
$$-3y + 4z = 4$$

$$\begin{bmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -3 & 4 \end{bmatrix}\begin{bmatrix} 0 \\ -1 \\ 4 \end{bmatrix}$$
$$A \qquad\qquad b$$

Each equation in a system of equations solutions can be
mapped to a plane. Then a line can be drawn through the
3 or more planes to find the solution to the system of equations.

$$x\begin{bmatrix} 2 \\ -1 \\ 0 \end{bmatrix} + y\begin{bmatrix} -1 \\ 2 \\ -3 \end{bmatrix} + 2\begin{bmatrix} 0 \\ -1 \\ 4 \end{bmatrix} = b\begin{bmatrix} 0 \\ -1 \\ 4 \end{bmatrix}$$
linear combination
$$x = 0 \quad y = 0 \quad 2 = 1$$

Column Picture

$$x\begin{bmatrix} 2 \\ -1 \end{bmatrix} + y\begin{bmatrix} -1 \\ 2 \end{bmatrix} = \begin{bmatrix} 0 \\ 3 \end{bmatrix}$$

Goal: Find the right linear Combination
to solve the system of equations.
$$1\begin{bmatrix} 2 \\ -1 \end{bmatrix} + 2\begin{bmatrix} -1 \\ 2 \end{bmatrix} = \begin{bmatrix} 0 \\ 3 \end{bmatrix}$$

$\Rightarrow 1 cd_1 + 2 cd_2 = (0,3)$

$b = \begin{bmatrix} 0 \\ 3 \end{bmatrix}$

$cd 1 \vec{x}$

Row Picture

Plane
$(0,0,1)$
$(0,3,0)$
$(1,0,0)$

row good for 2
row 3+ dims, unclear

$$\begin{bmatrix} 0 \\ -1 \\ 4 \end{bmatrix} cd3 = b\begin{bmatrix} 0 \\ -1 \\ 4 \end{bmatrix}$$

cd_1
cd_2
new $b_2 \begin{bmatrix} 0 \\ -1 \\ 3 \end{bmatrix}$

$$x \begin{bmatrix} 2 \\ -1 \\ 0 \end{bmatrix} + y \begin{bmatrix} -1 \\ 2 \\ -3 \end{bmatrix} + 2 \begin{bmatrix} 0 \\ -1 \\ 4 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ -3 \end{bmatrix}$$

$x = 1, \ y = 1, \ z = 0 \qquad (1,1,0) = b \begin{bmatrix} 1 \\ 1 \\ -3 \end{bmatrix}$

Can I solve $Ax = b$ for **every** b? in other words, do the linear combos of the columns fill 3 dimensional space?

for this matrix A, yes! $\Rightarrow$ invertible matrix

When can the linear combos **not** fill 3D space?

$\Rightarrow$ if all 3 vectors lie in the same plane: $Col \ 3 = Col_1 + Col_2$, noninvertible

Some matrix A × some vector $x = b$

$$Ax = b$$

$$\begin{bmatrix} 2 & 5 \\ 1 & 3 \end{bmatrix} \begin{bmatrix} 1 \\ 2 \end{bmatrix}$$

Two Ways: Column ways: $\begin{bmatrix} 1 \text{ of first column} \\ 2 \text{ of second column} \end{bmatrix} \begin{bmatrix} 2 \times 1 & 5 \times 2 \\ 1 \times 1 & 3 \times 2 \end{bmatrix} = \begin{bmatrix} 2 + 10 \\ 1 + 6 \end{bmatrix}$

$$1 \begin{bmatrix} 2 \\ 1 \end{bmatrix} + 2 \begin{bmatrix} 5 \\ 3 \end{bmatrix} = \begin{bmatrix} 12 \\ 7 \end{bmatrix}$$

Row Way: (dot product)

$$\begin{bmatrix} 2^{(1)} & 5^{(2)} \\ 1^{(1)} & 3^{(2)} \end{bmatrix} \begin{bmatrix} 1 \\ 2 \end{bmatrix} = \begin{bmatrix} 12 \\ 7 \end{bmatrix}$$

Mathematics for Machine Learning Ch 2.1

Linear Algebra — the study of how vectors interact with eachother in relation to space.

In general, vectors are objects that can be added together or multiplied by scalars to produce a new object of the same _dimension_

$\searrow$ vectors can only perform mathematical operations with another vector of the same dimension.

Examples of Vectors:

1) geometric vectors - directed segments $\vec{x}$ that allow us to perform operations using mathematical intuition regarding direction and magnitude. addition and scalar multiplication are operations of a geometric vector

2) Polynomials - can be added together resulting in a new polynomial (property 1) can be multiplied by a scalar, resulting in a polynomial. (property 2) Thus, polynomials are an unusual form of a vector

3) Audio Signals - represented as a series of numbers. can be added together, resulting in a new series of numbers (p1) we can scale an audio signal into another one (p2)

4) Elements of $\mathbb{R}^n$ (tuples of n real numbers). $\mathbb{R}^n$ is more abstract than polynomials

$$a = \begin{bmatrix} 1 \\ 2 \\ 3 \end{bmatrix} \in \mathbb{R}^3 \quad \text{is saying} \ a \ \text{is a tuple of 3 real numbers,}$$
and is a member of $\mathbb{R}^3$

Adding two vectors a,b $\in \mathbb{R}^n$ will result in a vector c $\in \mathbb{R}^n$
Multiplying a $\in \mathbb{R}^n$ by scalar $\lambda \in \mathbb{R}$ results in scaled vector $\lambda a \in \mathbb{R}^n$

Vectors $\in \mathbb{R}^n$ correspond loosely to an array of real numbers on a computer.

The idea of 'closure' - what is the set of all things that will result from my operation.

↳ in context of vectors. from MIT lecture - Can I solve $Ax=b$ for every b? [vector space]

Vector Mind Map:

Geometric Interpretation in my own words (prompt)

The visual / graphed representation of vectors. By graphing, we can see how adding two vectors together alters the segments they were. Or alternatively, we can see that going from tip to tail of $\vec{x}$ and $\vec{y}$ would result in the same as adding them together and then graphing. With scaling, we see the length of the vector scales, while the direction stays the same.

How are vectors different than points?

A point is a static "point" in a plane. It has no direction or magnitude (length). A vector has both direction and magnitude. A vector can also be scaled while a point stays the same. We can view a point as a location on a map, while a vector can be viewed as the path to get to a point.
